# Regulator View — Execution-Time Decision Record

Level 1 — $18M Wire Release • Banking Core Payment Governance

## Action proposed

An automated payments workflow proposed releasing an $18,000,000 wire transfer to a new beneficiary, relying on AI-driven sanctions screening and case disposition.

## Authority + outcome

Outcome: BLOCK.

Required authority: Treasury Release Authority + AML (dual control). Autonomy threshold was not met (sanctions ambiguity + KYC uncertainty), so release was blocked at the commit boundary.

## Bounds / safeguards enforced

Hard BLOCK at the settlement commit point (no partial release).

Automatic re■screening using current sanctions sources.

Time■boxed dual approval routing with explicit owners.

Evidence minted before any funds movement.

## Escalation path

A single approval packet was routed to Treasury + AML with the exact signals, thresholds, and required attestations. Release can only occur under signed dual control.

# Regulator View — Integrity + Audit Fields

What you can verify without asking us

## Integrity summary

This pack is composed of artefacts whose SHA■256 hashes are listed in a signed manifest.

If any byte is changed — even a single character — verification fails.

Pinned public key fingerprint: dd9d3312…6f26fe0d (full fingerprint in public_key.pem).

## Evidence fields included

Intent + parameters (amount, beneficiary status, mode)

Moment That Matters classification

Doctrine version + checks executed

Authority chain + escalation path

Outcome + any bounds (if allowed)

Enforcement record (what was blocked / applied)

Counterfactual impact summary

Integrity artefacts (signed manifest + hashes)

## Counterfactual

Without an execution-time gate, the wire would release under ambiguous sanctions screening; authority would be reconstructed after settlement via logs and testimony.
